SQL: more on joins, views, integrity constraints, types, and privileges

Last Lecture:

Examples on SQL, TRC and RA

Today:

Chapter 4

- Join expressions in SQL
- Views
- Integrity Constrains

Chapter 4: Intermediate SQL

- Join Expressions
- Views
- Transactions
- Integrity Constraints
- SQL Data Types and Schemas
- Authorization

Joined Relations

- Join operations take two relations and return as a result another relation.
- A join operation is a Cartesian product which requires that tuples in the two relations match (under some condition). It also specifies the attributes that are present in the result of the join
- The join operations are typically used as subquery expressions in the **from** clause

Join operations – Example

Relation course

course_id	title	dept_name	credits
BIO-301	Genetics	Biology	4
CS-190	Game Design	Comp. Sci.	4
CS-315	Robotics	Comp. Sci.	3

Relation prereq

course_id	prereg_id
BIO-301	BIO-101
CS-190	CS-101
CS-347	CS-101

Observe that

prereq information is missing for CS-315 and course information is missing for CS-437

Outer Join

- An extension of the join operation that avoids loss of information.
- Computes the join and then adds tuples form one relation that does not match tuples in the other relation to the result of the join.
- Uses null values.

Left Outer Join

course natural left outer join prereq

course_id	title	dept_name	credits	prereq_id
		Biology	4	BIO-101
CS-190	Game Design	Comp. Sci.	4	CS-101

student right outer join takes

Joined Relations

- Join operations take two relations and return as a result another relation.
- These additional operations are typically used as subquery expressions in the **from** clause
- Join condition defines which tuples in the two relations match, and what attributes are present in the result of the join.
- Join type defines how tuples in each relation that do not match any tuple in the other relation (based on the join condition) are treated.

Join types
inner join
left outer join
right outer join
full outer join

Full Outer Join

course natural full outer join prereq

course_id	title	dept_name	credits	prereg_id

Views

- In some cases, it is not desirable for all users to see the entire logical model (that is, all the actual relations stored in the database.)
- Consider a person who needs to know an instructors name and department, but not the salary. This person should see a relation described, in SQL, by

select ID, name, dept_name **from** instructor

- A view provides a mechanism to hide certain data from the view of certain users.
- Any relation that is not of the conceptual model but is made visible to a user as a "virtual relation" is called a view.

View Definition

- A view is defined using the create view statement which has the form
 create view v as < query expression >
 - where <query expression> is any legal SQL expression. The view name is represented by *v*.
- Once a view is defined, the view name can be used to refer to the virtual relation that the view generates.
- View definition is not the same as creating a new relation by evaluating the query expression
 - Rather, a view definition causes the saving of an expression; the expression is substituted into queries using the view.

Example Views

- A view of instructors without their salary create view faculty as select ID, name, dept_name from instructor
- Find all instructors in the Biology department select name from faculty where dept_name = 'Biology'
- Create a view of department salary totals
 create view departments_total_salary(dept_name, total_salary) as
 select dept_name, sum (salary)
 from instructor
 group by dept_name;

Views Defined Using Other Views

```
    create view physics fall 2015 as

   select course.course id, sec id, building, room number
   from course, section
   where course.course id = section.course id
          and course.dept name = 'Physics'
          and section.semester = 'Fall'
          and section.year = '2015';

    create view physics fall 2015 Smith as

    select course id, room number
    from physics_fall_2015
    where building='Smith';
```

View Expansion

```
create view physics_fall_2015_Smith as
(select course_id, room_number
from (select course.course_id, building, room_number
    from course, section
    where course.course_id = section.course_id
        and course.dept_name = 'Physics'
        and section.semester = 'Fall'
        and section.year = '2015')
where building= 'Watson';
```

Views Defined Using Other Views

- One view may be used in the expression defining another view
- A view relation v_1 is said to depend directly on a view relation v_2 if v_2 is used in the expression defining v_1
- A view relation v_1 is said to depend on view relation v_2 if either v_1 depends directly to v_2 or there is a path of dependencies from v_1 to v_2
- A view relation v is said to be recursive if it depends on itself.

Example Recursive View

```
CREATE RECURSIVE VIEW reporting line (employee id, subor-
dinates) AS
SELECT
employee id,
full_name AS subordinates
FROM
employees
WHERE
manager id IS NULL
UNION ALL
SELECT
e.employee_id,
rl.subordinates || ' > ' || e.full name
AS subordinates
FROM
employees e
INNER JOIN reporting line rl ON e.manager id =
rl.employee id;
```

Example Query

```
SELECT
subordinates
FROM
reporting_line
WHERE
employee id = 10;
```

Results

```
Michael North > Sarah Berry > Carolyn Henderson (1 row)
```

View Expansion

- A way to define the meaning of views defined in terms of other views.
- Let view v_1 be defined by an expression e_1 that may itself contain uses of view relations.
- View expansion of an expression repeats the following replacement step:

repeat

Find any view relation v_i in e_1 Replace the view relation v_i by the expression defining v_i **until** no more view relations are present in e_1

 As long as the view definitions are not recursive, this loop will terminate

Update of a View

Add a new tuple to faculty view which we defined earlier
 insert into faculty values ('30765', 'Green', 'Music');
 This insertion must be represented by the insertion of the tuple

('30765', 'Green', 'Music', null)

into the *instructor* relation

Some Updates cannot be Translated Uniquely

- create view instructor_info as select ID, name, building from instructor, department where instructor.dept_name= department.dept_name;
- insert into instructor_info values ('69987', 'White', 'Taylor');
 - which department, if multiple departments in Taylor?
 - what if no department is in Taylor?
- Most SQL implementations allow updates only on simple views
 - The **from** clause has only one database relation.
 - The select clause contains only attribute names of the relation, and does not have any expressions, aggregates, or distinct specification.
 - Any attribute not listed in the select clause can be set to null
 - The query does not have a **group** by or **having** clause.

And Some Not at All

- create view history_instructors as select * from instructor where dept_name= 'History';
- What happens if we insert ('25566', 'Brown', 'Biology', 100000) into history_instructors?
- In postgreSQL, we may use WITH [Local|CASCADED] CHECK OPTION to prevent it

```
create view history_instructors as
  select *
  from instructor
  where dept_name= 'History' with check option;
```

Materialized Views

 Materializing a view: create a physical table containing all the tuples in the result of the query defining the view Use CREATE MATERIALIZED VIEW

- If relations used in the query are updated, the materialized view result becomes out of date
 - Need to maintain the view, by updating the view whenever the underlying relations are updated.

Transactions

- Unit of work
- Atomic transaction
 - either fully executed or rolled back as if it never occurred
- Isolation from concurrent transactions
- Transactions begin implicitly
 - Ended by commit work or rollback work
- But default on most databases: each SQL statement commits automatically
 - Can turn off auto commit for a session (e.g. using API)
 - In SQL:1999, can use: begin atomic end
 - Not supported on most databases

Integrity Constraints

- Integrity constraints guard against accidental damage to the database, by ensuring that authorized changes to the database do not result in a loss of data consistency.
 - A checking account must have a balance greater than \$10,000.00
 - A salary of a bank employee must be at least \$20.00 an hour
 - A customer must have a (non-null) phone number

Integrity Constraints on a Single Relation

- not null
- primary key
- unique
- check (P), where P is a predicate

Not Null and Unique Constraints

not null

Declare name and budget to be not null

name varchar(20) not null budget numeric(12,2) not null

- unique (A₁, A₂, ..., A_m)
 - The unique specification states that the attributes A1, A2, ...
 Am
 form a candidate key.
 - Candidate keys are permitted to be null (in contrast to primary keys).

The check clause

check (P)where P is a predicate

Example: ensure that semester is one of fall, winter, spring or summer:

```
create table section (
    course_id varchar (8),
    sec_id varchar (8),
    semester varchar (6),
    year numeric (4,0),
    building varchar (15),
    room_number varchar (7),
    time slot id varchar (4),
    primary key (course_id, sec_id, semester, year),
    check (semester in ('Fall', 'Winter', 'Spring', 'Summer'))
);
```

Referential Integrity

- Ensures that a value that appears in one relation for a given set of attributes also appears for a certain set of attributes in another relation.
 - Example: If "Biology" is a department name appearing in one of the tuples in the *instructor* relation, then there exists a tuple in the *department* relation for "Biology".
- Let A be a set of attributes. Let R and S be two relations that contain attributes A and where A is the primary key of S. A is said to be a **foreign key** of R if for any values of A appearing in R these values also appear in S.

Cascading Actions in Referential Integrity

```
    create table course (

    course id char(5) primary key,
    title varchar(20),
    dept name varchar(20) references department

    create table course (

    dept name varchar(20),
    foreign key (dept_name) references department
           on delete cascade
           on update cascade,
• alternative actions to cascade: set null, set default
```

Integrity Constraint Violation During Transactions

• E.g.

```
create table person (
ID char(10),
name char(40),
mother char(10),
father char(10),
primary key ID,
foreign key father references person,
foreign key mother references person)
```

- How to insert a tuple without causing constraint violation?
 - insert father and mother of a person before inserting person
 - OR, set father and mother to null initially, update after inserting all persons (not possible if father and mother attributes declared to be **not null**)

Complex Check Clauses

- check (time_slot_id in (select time_slot_id from time_slot))
- Every section has at least one instructor teaching the section.
 - how to write this?
- Unfortunately: subquery in check clause not supported by pretty much any database
 - Alternative: triggers (later)
- create assertion <assertion-name> check check check ;
 - Also not supported by anyone

Built-in Data Types in SQL

- date: Dates, containing a (4 digit) year, month and date
 - Example: **date** '2005-7-27'
- time: Time of day, in hours, minutes and seconds.
 - Example: **time** '09:00:30' **time** '09:00:30.75'
- timestamp: date plus time of day
 - Example: **timestamp** '2005-7-27 09:00:30.75'
- interval: period of time
 - Example: interval '1' day
 - Subtracting a date/time/timestamp value from another gives an interval value
 - Interval values can be added to date/time/timestamp values

Index Creation

- create table student
 (ID varchar (5),
 name varchar (20) not null,
 dept_name varchar (20),
 tot_cred numeric (3,0) default 0,
 primary key (ID))
- create index studentID_index on student(ID)
- Indices are data structures used to speed up access to records with specified values for index attributes
 - e.g. select *
 from student
 where ID = '12345'

can be executed by using the index to find the required record, without looking at all records of *student*

More on indices in Chapter 11

Domains

 create domain construct in SQL-92 creates user-defined domain types

create domain person_name char(20) not null

- Types and domains are similar. Domains can have constraints, such as **not null**, specified on them.
- create domain degree_level varchar(10)
 constraint degree_level_test
 check (value in ('Bachelors', 'Masters', 'Doctorate'));

Large-Object Types

- Large objects (photos, videos, CAD files, etc.) are stored as a large object:
 - blob: binary large object -- object is a large collection of uninterpreted binary data (whose interpretation is left to an application outside of the database system)
 - clob: character large object -- object is a large collection of character data
 - When a query returns a large object, a pointer is returned rather than the large object itself.

Authorization

Forms of authorization on parts of the database:

- Read allows reading, but not modification of data.
- Insert allows insertion of new data, but not modification of existing data.
- **Update** allows modification, but not deletion of data.
- Delete allows deletion of data.

Forms of authorization to modify the database schema

- Index allows creation and deletion of indices.
- Resources allows creation of new relations.
- Alteration allows addition or deletion of attributes in a relation.
- **Drop** allows deletion of relations.

Authorization Specification in SQL

The grant statement is used to confer authorization

```
grant <privilege list>
on <relation name or view name> to <user list>
```

- <user list> is:
 - a user-id
 - public, which allows all valid users the privilege granted
 - A role (more on this later)
- Granting a privilege on a view does not imply granting any privileges on the underlying relations.
- The grantor of the privilege must already hold the privilege on the specified item (or be the database administrator).

Privileges in SQL

- select: allows read access to relation, or the ability to query using the view
 - Example: grant users U_1 , U_2 , and U_3 **select** authorization on the *instructor* relation:

grant select on instructor to U_1 , U_2 , U_3

- insert: the ability to insert tuples
- update: the ability to update using the SQL update statement
- **delete**: the ability to delete tuples.
- all privileges: used as a short form for all the allowable privileges

Revoking Authorization in SQL

- The **revoke** statement is used to revoke authorization.
 - revoke <privilege list>
 - on <relation name or view name> from <user list>
- Example:
 - revoke select on branch from U_1 , U_2 , U_3
- <privilege-list> may be all to revoke all privileges the revokee may hold.
- If <revokee-list> includes public, all users lose the privilege except those granted it explicitly.
- If the same privilege was granted twice to the same user by different grantees, the user may retain the privilege after the revocation.
- All privileges that depend on the privilege being revoked are also revoked.

Roles

- create role instructor;
- grant instructor to Harold;
- Privileges can be granted to roles:
 - grant select on takes to instructor;
- Roles can be granted to users, as well as to other roles
 - create role teaching assistant
 - grant teaching_assistant to instructor;
 - Instructor inherits all privileges of teaching_assistant
- Chain of roles
 - create role dean;
 - grant instructor to dean;
 - grant dean to Duerk;

Authorization on Views

- create view geo_instructor as
 (select *
 from instructor
 where dept_name = 'Geology');
- grant select on geo_instructor to geo_staff
- Suppose that a geo staff member issues
 - select *from geo instructor;
- What if
 - geo_staff does not have permissions on instructor?
 - creator of view did not have some permissions on instructor?
